

NEW ZEALAND THREAT CLASSIFICATION SERIES 27

Conservation status of New Zealand indigenous lichens and lichenicolous fungi, 2018

Peter de Lange, Dan Blanchon, Allison Knight, John Elix, Robert Lücking, Kelly Frogley,
Anna Harris, Jerry Cooper and Jeremy Rolfe

Cover: *Pseudocycphellaria faveolata*, Not Threatened, is widespread throughout New Zealand. Photo: Robert Lücking.

New Zealand Threat Classification Series is a scientific monograph series presenting publications related to the New Zealand Threat Classification System (NZTCS). Most will be lists providing NZTCS status of members of a plant or animal group (e.g. algae, birds, spiders), each assessed once every 5 years. From time to time the manual that defines the categories, criteria and process for the NZTCS will be reviewed. Publications in this series are considered part of the formal international scientific literature.

This report is available from the departmental website in pdf form. Titles are listed in our catalogue on the website, refer www.doc.govt.nz under *Publications*.

Abstract

The conservation status of all known New Zealand lichen and lichenicolous fungus taxa was reassessed using the New Zealand Threat Classification System (NZTCS). The names of 176 taxa have changed, 233 taxa have been added to the list and 10 have been removed from it since the 2010 assessment, making a total of 2026 taxa listed in this report. Assessments have been completed for 91 taxa that were previously Data Deficient. Of these, 1 was assessed as Threatened – Nationally Critical, 82 were At Risk – Naturally Uncommon and 8 Not Threatened. However, 19 taxa that were previously assessed At Risk – Naturally Uncommon or Not Threatened are now assessed as Data Deficient. Of the newly added taxa, 211 are also assessed as Data Deficient. Other changes include 8 taxa that were previously assessed as Naturally Uncommon, which now have a worse status: 1 Threatened – Nationally Endangered, 2 Threatened – Nationally Vulnerable, and 5 At Risk – Declining. Of 9 taxa that were previously assessed as Not Threatened, 2 are now Declining and 8 are now Naturally Uncommon. An improved status has been assessed for 7 taxa: 2 that were previously assessed as Nationally Endangered are now Nationally Vulnerable, and 5 that were previously Naturally Uncommon are now Not Threatened. The majority of the lichenised mycobiota indigenous to New Zealand remain poorly known. However, the need for further biosystematic investigation is hampered by the lack of New Zealand lichen expertise. A full list of New Zealand's lichenised mycobiota (as of August 2018) is presented, along with a statistical summary and brief notes on the most important changes. This list replaces all previous NZTCS lists for lichens.

Keywords: Galloway, New Zealand Threat Classification System, NZTCS, conservation status, crustose lichens, foliose lichens, fruticose lichens, Caliciaceae, Cladoniaceae, Graphidaceae, Lecanoraceae, Lecideaceae, Lobariaceae, Pannariaceae, Parmeliaceae, Pertusariaceae, Physciaceae, Ramalinaceae, Teloschistaceae, Trapeliaceae, Verrucariaceae

1. Summary

The conservation status of 2027 New Zealand lichenised and lichenicolous mycobiota (including unnamed entities designated with informal ‘tag’ names) was assessed using the New Zealand Threat Classification System (NZTCS) criteria of Townsend et al. (2008). This replaces the 2010 assessment of lichen taxa (de Lange et al. 2012; see also www.nztc.org.nz/#/reports/21).

The conservation status categories and criteria applied here are summarised in Section 2, which presents the complete lists of taxa arranged by conservation status. The 2,027 taxa plus 10 that have been removed since the 2010 assessment (de Lange et al. 2012) can also be found at www.nztc.org.nz/#/reports/55.

1.1 Taxonomic changes

The list of taxa assessed in 2010 (de Lange et al. 2012) relied heavily on the work of the late David Galloway who died in December 2014 (de Lange 2014). To ensure that this new report is as comprehensive as possible following this loss, the panel has broadened to include international lichenologists, who are placing increasing attention on the taxonomy of New Zealand lichenised mycobiota.

For instance, in 2015 the Field Museum, Chicago, in collaboration with New Zealand experts, began a study into the New Zealand Lobariaceae, which is ostensibly one of the best studied lichen families in the country (Galloway 1985, 1988, 1997, 2007; Thomas et al. 2002). The initiation of this research has revealed unexpected diversity of new species, and consequent problems with the application of some well known names as well as the need to merge others (Lücking & Moncada 2018; Ranft et al. 2018).

These taxonomic changes affect conservation status assessments, as previously broad concepts of New Zealand species follow a world-wide trend in which hitherto widespread species have been segregated into multiple narrow-range regional endemics (Moncada et al. 2014; Del-Prado et al. 2016; Lücking et al. 2017c).

The impact of using molecular systematics to resolve New Zealand lichen diversity, as well as ongoing studies based on chemistry and morphology, can be seen in the names of 176 taxa that have changed (Table 1) and in the addition of 233 taxa to this report (Table 2) compared with de Lange et al. (2012). Also, systematic studies using molecular data resulted in much adjusted family-level classifications, summarised in Lücking et al. (2017a, b) and Diederich & Lawrey (2018) and applied here.

Table 1. Names in de Lange et al. (2012) that have changed for this report. Names listed below have changed because the identification of New Zealand material has been reconsidered or because taxonomic concepts have changed.

NAME IN 2010 (DE LANGE ET AL. 2012)	NAME IN THIS DOCUMENT	FAMILY
“Dendriscocaulon dendroides” (Nyl.) R.Sant. ex H.Magn.	<i>Sticta dendroides</i> (Nyl.) Moncada, Lücking & de Lange	Lobariaceae
<i>Acarospora schleicheri</i> (Ach.) A.Massal.	<i>Acarospora citrina</i> (Taylor) Zahlbr. ex Rech.	Acarosporaceae
<i>Amandinea insperata</i> (Nyl.) H.Mayrhofer & Ropin	<i>Orcularia insperata</i> (Nyl.) Kalb & Giralt	Caliciaceae
<i>Amandinea lecideina</i> (H.Mayrhofer & Poelt) Scheid. & H.Mayrhofer	<i>Amandinea pelidna</i> (Ach.) Fryday & L.Arcadia	Caliciaceae

<i>Xenolecia cataractarum</i> Fryday	Lecideaceae

Since the 2010 assessment (de Lange et al. 2012), ten taxa have been removed from the list. Six that are now not considered to occur in New Zealand were based on misidentifications or on adjusted species concepts. Taxonomic research has recognised that the New Zealand specimens considered to be *Buellia epigaea* and *Pseudocyphellaria crocata* are, in fact, distinct from them (Table 3). The New Zealand *Buellia* that was previously assessed as *B. epigaea* has been described and named *B. suttonensis*. Molecular studies have shown that the presumably widespread and common New Zealand lichen *Pseudocyphellaria crocata* is now considered to represent at least four species, all endemic, with the recognition that *P. crocata* sens. str. itself is not present in New Zealand (Lücking & Moncada 2018; Moncada et al. unpubl. data).

Buellia demutans, *B. tetrapla*, and *Laurera cumingii* (now as *Marcelaria cummingii*) were listed in Galloway (2007) but specimens cannot be found to support these records. For now they are excluded here from the lichenised mycobiota of New Zealand. Furthermore, the habitat descriptions in Galloway (2007) do not match the known habitats of these taxa in Australia (J. Elix unpubl. data.). The taxon listed as *Icmadophila ericetorum* in de Lange et al. (2012) has been redetermined as *Dibaeis absoluta*. Four taxa are considered to be not distinct from other taxa in this report (Table 4).

Studies using molecular systematics, though still in their infancy, are essential to understand the taxonomy of New Zealand lichenised mycobiota, which has hitherto been mainly based on morphological and chemical distinctions. As these studies continue and expand into other families and genera, further taxonomic changes are anticipated and stability of the names used for New Zealand lichenised mycobiota is unlikely for some years yet. This will likely apply even

Table 3. Taxa listed in de Lange et al. (2012) that had been misidentified and do not occur in New Zealand.

within such well-researched families as the Lobariaceae and Parmeliaceae, or at genus level (e.g. *Caloplaca*, *Cladia*, *Lecanora*, *Ramalina*), (Arup et al. 2013; Blanchon et al. 2015; Ferencova et al. 2014; Hayward et al. 2014; Parmmen et al. 2013; Printzen et al. 2017; Ranft et al. 2018; see also Table 1).

1.2 Trends

Table 5 compares the number of taxa in each conservation status in the 2010 assessment (de Lange et al. 2012) with the 2018 assessment (this report). Table 6 shows where status changes have occurred between the two assessments. Of the 975 taxa that were reported as being Data Deficient in 2010 (de Lange et al. 2012), 91 have been assessed in this report. Of these, 1 is Threatened – Nationally Critical, 82 are At Risk – Naturally Uncommon, and 8 are Not Threatened. Conversely, 19 taxa that were assessed as either Naturally Uncommon or Not Threatened by de Lange et al. (2012) are listed as Data Deficient in this report.

Table 5. Statistical summary of the status of New Zealand lichen taxa assessed in 2010 (de Lange et al. 2012) and 2018 (this document).

CONSERVATION STATUS	2010	2017
Data Deficient	975	1108
Threatened – Nationally Critical	4	6
Threatened – Nationally Endangered	4	2
Threatened – Nationally Vulnerable	3	8
At Risk – Declining	4	10
At Risk – Naturally Uncommon	174	249
Not Threatened	639	644
Total	1803	2026

Table 6. Summary of status changes of lichen taxa between 2010 (data in rows, de Lange et al. 2012) and 2018 (data in columns, this report). Numbers to the right of the diagonal (shaded dark grey) indicate improved status (e.g. two taxa have moved from Nationally Endangered in 2010 to Nationally Vulnerable in 2018), numbers to the left of the diagonal (shaded light grey) indicate poorer status, numbers on the diagonal (shaded black) have not changed, and numbers without shading are either taxa that have moved into or out of Data Deficient, taxa added to this assessment, taxa rejected from this assessment because they had been misidentified as taxa that are now known not to occur in New Zealand (NA) or they are no longer considered to be distinct (TI) from other taxa.

		Conservation status 2018									
		Total 2026	DD 1107	NC 6	NE 2	NV 8	DEC 10	NU 249	NT 644	NA ¹ 6	TI ² 4
Conservation status 2010	Data Deficient (DD)	975	879	1				82	8	3	2
	Nationally Critical (NC)	4		4							
	Nationally Endangered (NE)	4			1	2				1	
	Nationally Vulnerable (NV)	3				3					
	Declining (Dec)	4					4				
	Naturally Uncommon (NU)	174	15		1	2	4	145	5	1	1
	Not Threatened (NT)	639	4				2	8	623	1	1
	Not listed	233	209	1		1		14	8		

¹ NA = Not Assessed (see Table 3).

² TI = Taxonomically Indistinct (see Table 4).

Figure 1. *Ramalina canariensis* is now At Risk – Declining because of observed deterioration of its population on Chatham Island. Photo: Peter J. de Lange.

In this report, six taxa have been reassessed with an improved status since the 2010 assessment (de Lange et al. 2012), all because of a better understanding about their populations rather than any observed population increases. A worsening status has been assessed for seven taxa in this report. Three of the changes are based on better knowledge about their condition, but actual decline is reported for *Cladonia fuliginosa*, *Notocladonia cochleata*, *Ramalina canariensis* (Fig. 1) and *R. geniculata*.

The causes of decline in New Zealand lichens are not well studied but, with the exception of *Ramalina geniculata*, the declines can be directly linked to the loss of habitat. For example, *Notocladonia cochleata* is a species of open gumland vegetation, clay hard pans, subalpine scrub and serpentinite soils. It has declined markedly in the northern part of its New Zealand range through habitat loss to forestry, farmland, vegetation succession and competition from flowering plant weed species (such as *Aristea ecklonii*).

The decline of *Cladonia fuliginosa* can be directly attributed to habitat loss from coal mining at its stronghold on the Stockton Plateau.

The decline in New Zealand of *Ramalina canariensis* is less clear, though this species has only ever been common on the Chatham Islands (Bannister et al. 2004; P.J. de Lange unpubl. data). However, the main phorophyte (plant the lichen grows on) for *R. canariensis* on those islands, akeake (*Olearia traversiorum*), has continued to decline over the last decade (de Lange et al. 2013; de Lange et al. 2018), resulting in a slight decline of *R. canariensis*, sufficient to shift this species from At Risk – Naturally Uncommon to At Risk – Declining. There is also some indication that *R. canariensis* is declining from the northern North Island part of its range, where it is usually associated with mangrove (*Avicennia marina* subsp. *australisica*). The reasons for this decline are less clear, though clearance of mature mangrove along parts of the Kaipara Harbour has reduced its range there. This also seems to be the case for *Ramalina geniculata*

where a decline has been detected in its northern North Island range. This observation stems from a comprehensive study of the lichens inhabiting mangroves (*Avicennia marina* subsp. *australasica*) in which *R. geniculata* was recorded in 12 of the 20 mangrove communities sampled (Reynolds et al. 2017). The authors of that paper noted that this was a ‘previously common species’ based on data presented in Blanchon et al. (1996) and Bannister et al. (2004), and it was ‘known to be common in stands of *Avicennia marina* from Auckland northwards’. As yet there is no clear cause of this decline, as old-age stands of the phorophyte host remain widespread and common in this part of New Zealand (de Lange & de Lange 1994).

1.3 Research

Despite the large number of Data Deficient taxa (1108, an increase of 133 taxa on the previous assessment), the 2010 report (de Lange et al. 2012) achieved its goal of highlighting New Zealand’s lichenised and lichenicolous mycobiota and their vulnerability. This in turn has increased the number of people surveying for them, in some cases resulting in more definite conservation status assessments (e.g. *Caloplaca allanii* (Fig. 2); Sparkes et al. 2014). Although lichenology is scarcely

taught in New Zealand’s universities, the number of amateurs taking up the subject as a hobby and the expansion of the annual John Child Bryophyte workshops to include lichens (the workshop is now known as the ‘John Child Bryophyte and Lichen Workshop’) is encouraging. Similarly, many of New Zealand’s botanical societies are now undertaking ‘Lichen Workshops’, and lichens are now being collected widely in regional BioBlitzes. The recent publication of a field guide to some of New Zealand’s lichen diversity (Knight 2014) is also helping to encourage lichenology and widen the scope of potential lichen observers. Further,

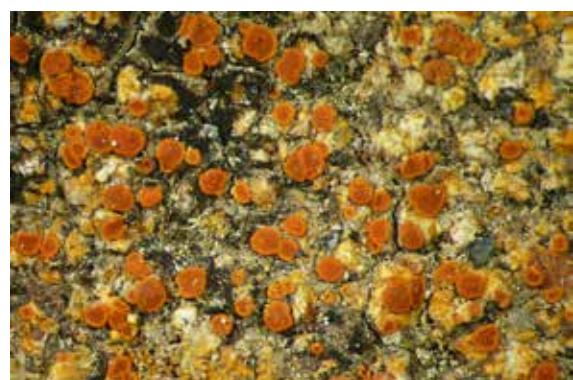

Figure 2. The previously Data Deficient *Caloplaca allanii* has been assessed as Threatened – Nationally Critical based on improved knowledge as more people become aware of lichens and lichen conservation. Photo: Dan Blanchon.

New Zealand now has a dedicated lichen herbarium (de Lange & Blanchon 2018). These changes are resulting in an increased awareness of ‘lichens’ and resulting in new discoveries, range expansions and other information that have allowed for better conservation status assessments.

This increased awareness has not only helped with resolving Data Deficient listings but also in resolving the conservation status of such species as *Austropeltum glareosum*, *Pycnothelia calignosa* and *Ramalina pacifica*, which have shifted from Nationally Endangered to Nationally Vulnerable. These are changes that stem from people’s observations of them in the wild – positive result from the initial report on the conservation status of New Zealand lichenised and lichenicolous mycobiota by de Lange et al. (2012).

The taxonomy of New Zealand lichenised and lichenicolous mycobiota remains a key focus of research, but dedicated survey, including sampling from specific phorophytes (e.g. Reynolds et al. 2017) and habitats is needed to assess the conservation status of Data Deficient taxa. Such work also helps to reveal the true extent of New Zealand’s lichenised and lichenicolous mycobiota. For example, a survey of the Auckland Region’s reserve network using a systematic quadrat-based sampling of indigenous vegetation resulted in the addition of *Pertusaria endoxantha* to the New Zealand lichen Flora (Marshall & Blanchon 2017).

2. Conservation status of New Zealand lichens and lichenicolous fungi

This section documents the lichenised and lichenicolous mycobiota of the New Zealand Botanical Region (as defined by Allan 1961). The names and nomenclature used are based on what the panel members assessed in 2010 (de Lange et al. 2012) with additions and updates contributed by international linchenologists until August 2018. Taxa were assessed according to the criteria of Townsend et al. (2008), grouped by conservation status, then alphabetically by scientific name. Data Deficient taxa are listed first mainly because they are very seldom seen, so most are likely to end up being considered threatened and some may already be extinct. Categories are ordered by degree of loss, with Nationally Critical at the top of the list and Not Threatened at the bottom.

2.1 Decline rates

Decline rates are recorded as ranges (e.g. 10–50%, 50–70%) that define thresholds for status change. These thresholds are relative to population size and are considered over three generations (with a minimum of 10 years) of the taxon being assessed. Taxa that have very large populations may sustain higher decline rates than taxa that have smaller populations before they move into a worse category.

2.1.1 Qualifiers

See Townsend et al. (2008) for details of criteria and qualifiers, which are abbreviated as follows:

CD	Conservation Dependent
De	Designated
DP	Data Poor
EF	Extreme Fluctuations
EW	Extinct in the Wild
IE	Island Endemic
Inc	Increasing
OL	One Location
PD	Partial Decline
RF	Recruitment Failure
RR	Range Restricted
SO	Secure Overseas
Sp	Sparse
St	Stable
TO	Threatened Overseas

2.2 Status change and reason for change

The status of a taxon that has been previously assessed may change for the better (less threatened), worse (more threatened) or, if the taxon moved into or out of Data Deficient, the change is neutral – neither better nor worse but reflecting the level of knowledge about its status. Taxa that are assessed for the first time are recorded as ‘new listing’.

Status changes are made for several reasons: actual observed improvement or worsening of populations, more knowledge now available about the state of populations, or reinterpretation of the existing data that informed previous assessments. The reason ‘greater uncertainty’ is used for taxa that have been previously assessed but for which the panel now lacks relevant information to maintain an assessment.

Data Deficient (1108)

Taxa that are suspected to be threatened or, in some instances, possibly extinct, but are not definitely known to belong to any particular category due to a lack of current information about their distribution and abundance. It is hoped that listing such taxa will stimulate research to find out the true category (for a fuller definition see Townsend et al. 2008).

Threatened (16)

Taxa that meet the criteria specified by Townsend et al. (2008) for the categories Nationally Critical, Nationally Endangered and Nationally Vulnerable.

Nationally Critical (6)

Criteria for Nationally Critical:

A – very small population (natural or unnatural)

- A(1) <250 mature individuals
- A(2) ≤2 subpopulations, ≤200 mature individuals in the larger subpopulation
- A(3) Total area of occupancy ≤1 ha (0.01 km²)

B – small population (natural or unnatural) with an ongoing or forecast decline of 50–70% over 3 generations (minimum 10 years)

- B(1) 250–1000 mature individuals
- B(2) ≤5 subpopulations, ≤300 mature individuals in the largest subpopulation
- B(3) Total area of occupancy ≤10 ha (0.1 km²)

C – population (irrespective of size or number of subpopulations) with an ongoing or forecast decline of >70% over 3 generations (minimum 10 years)

C Predicted decline >70%

Nationally Endangered (2)

Criteria for Nationally Endangered:

A – small population that has an ongoing or forecast decline of 10–50% over 3 generations (minimum 10 years)

- A(1) 250–1000 mature individuals
- A(2) ≤5 subpopulations, ≤300 mature individuals in the largest subpopulation
- A(3) Total area of occupancy ≤10 ha (0.1 km²)

B – unnaturally small population that has an ongoing or forecast stable state of ±10% over 3 generations (minimum 10 years)

- B(1) 250–1000 mature individuals
- B(2) ≤5 subpopulations, ≤300 mature individuals in the largest subpopulation
- B(3) Total area of occupancy ≤10 ha (0.1 km²)

C – moderate population that has an ongoing or forecast decline of 50–70% over 3 generations (minimum 10 years)

- C(1) 1000–5000 mature individuals
- C(2) ≤15 subpopulations, ≤500 mature individuals in the largest subpopulation
- C(3) Total area of occupancy ≤100 ha (1 km²)

Nationally Vulnerable (8)

Criteria for Nationally Vulnerable:

A – unnaturally small population that has an ongoing or forecast increase of >10% over 3 generations (minimum 10 years)

- A(1) 250–1000 mature individuals
- A(2) ≤5 subpopulations, ≤300 mature individuals in the largest subpopulation
- A(3) Total area of occupancy ≤10 ha (0.1 km²)

B – unnaturally moderate-size population that has an ongoing or forecast stable state of ±10% over 3 generations (minimum 10 years)

- B(1) 1000–5000 mature individuals, stable population
- B(2) ≤15 subpopulations, ≤500 mature individuals in the largest subpopulation, stable population
- B(3) Total area of occupancy ≤100 ha (1 km²), stable population

C – moderate population that has an ongoing or forecast decline of 10–50% over 3 generations (minimum 10 years)

- C(1) 1000–5000 mature individuals
- C(2) ≤15 subpopulations, ≤500 mature individuals in the largest subpopulation
- C(3) Total area of occupancy ≤100 ha (1 km²)

D – moderate to large population that has an ongoing or forecast decline of 30–70% over 3 generations (minimum 10 years)

- D(1) 5000–20 000 mature individuals
- D(2) ≤15 subpopulations, ≤1000 mature individuals in the largest subpopulation
- D(3) Total area of occupancy ≤1000 ha (10 km²)

E – large population that has an ongoing or forecast decline of 50–70% over 3 generations (minimum 10 years)

- E(1) 20 000–100 000 mature individuals
- E(2) Total area of occupancy ≤10 000 ha (100 km²)

At Risk (259)

Taxa that meet the criteria specified by Townsend et al. (2008) for Declining, Recovering, Relict and Naturally Uncommon.

Declining (10)

Criteria for Declining:

A – moderate to large population that has an ongoing or forecast decline of 10–30% over 3 generations (minimum 10 years)

- A(1/1) 5000–20 000 mature individuals
- A(2/1) Total area of occupancy ≤1000 ha (10 km²)

B – large population that has an ongoing or forecast decline of 10–50% over 3 generations (minimum 10 years)

- B(1/1) 20 000–100 000 mature individuals
- B(2/1) Total area of occupancy ≤10 000 ha (100 km²)

C – very large population that has an ongoing or forecast decline of 10–70% over 3 generations (minimum 10 years)

- C(1/1) >100 000 mature individuals
- C(2/1) Total area of occupancy >10 000 ha (100 km²)

Recovering (0)

Taxa that have undergone a documented decline within the last 1000 years and now have an ongoing or forecast increase of >10% in the total population or area of occupancy, taken over the

next 10 years or three generations, whichever is longer. Note that such taxa that are increasing but have a population size of <1000 mature individuals (or total area of occupancy of <10 ha) are listed in one of the Threatened categories, depending on their population size (for more details see Townsend et al. (2008)).

Criteria for Recovering:

- A 1000–5000 mature individuals or total area of occupancy ≤100 ha (1 km²), and predicted increase >10%
- B 5000–20 000 mature individuals or total area of occupancy ≤1000 ha (10 km²), and predicted increase >10%

Relict (O)

Taxa that have undergone a documented decline within the last 1000 years, and now occupy <10% of their former range and meet one of the following criteria:

- A 5000–20 000 mature individuals; population stable ($\pm 10\%$)
- B >20 000 mature individuals; population stable or increasing at >10%

The range of a relictual taxon takes into account the area currently occupied as a ratio of its former extent. Relict can also include taxa that exist as reintroduced and self-sustaining populations within or outside their former known range (for more details see Townsend et al. (2008)).

Naturally Uncommon (249)

Taxa whose distribution is confined to a specific geographical area or which occur within naturally small and widely scattered populations, where this distribution is not the result of human disturbance.

3. Acknowledgements

This report is dedicated to the memory of Dr David J. Galloway M.Sc., Ph.D., D.Sc. (Otago), FRSNZ, FLS, FRGS, CBiol, MIBiol (1942–2014), a valued friend, mentor and lichenophile who did so much for New Zealand lichens. The loss of David Galloway has not only impacted on our understanding of lichen diversity in an ecological context but also the field of biosystematics, particularly correct species recognition of lichen fungi in New Zealand. This in turn has affected our management capabilities regarding lichens. The fact that we were able to undertake a second conservation status assessment serves to demonstrate the strength of the foundations David set for New Zealand lichenology.

The authors also wish to thank the many New Zealanders who have taken an interest in lichens, started to collect or observe them, and who have drawn their finds to our attention. In particular we thank Catherine Beard, Daniel Bennett, Orhan Er, Marley Ford, Dave Houston, Sarah Killick, Andrew Marshall, Tim Martin, Hayley Nessia, Kamera Raharaha, Christy Reynolds, Philip Simpson, Jon Terry, Mikey Watson and Carol West for their many collections, surveys for ‘Data Deficient’ lichens and new lichen discoveries. For comments on the taxonomy of specific families and genera we acknowledge help received from Dr(s) Bibiana Moncada, Thorsten Lumbsch, Bernard Goffinet, Christian Printzen, Alan Fryday and Matts Wedin.
